

THE AVALANCHE HAZARD WILL BE CONSIDERABLE

Avalanche Hazard Forecast for Saturday 13/02/2021

Avalanche Problems

Wind Slab

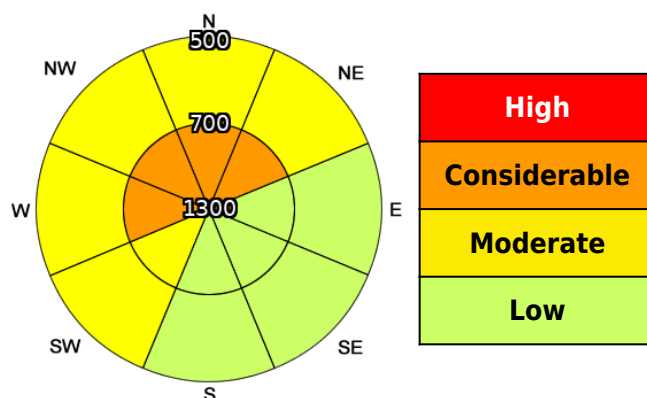

Persistent Weak Layers

Cornices

Forecast Snow Stability & Avalanche Hazard

Avalanches likely on W to N aspects mostly above 700m. On these aspects at lower levels and above 500m unstable windslab will continue to develop on steep banks and gullies. Greatest instability in all these areas will be within steep and convex terrain. Instabilities on SW and NE aspects due to cross loading. In steep convex areas weaknesses will remain at depth above 500 metres on W to N aspects. This will be mostly bridged by the old hard windslab. The avalanche hazard will be Considerable.

Forecast Weather Influences

Cold with snow showers at all levels, this will peter out during the night. Gale to storm force South-South-Easterly winds will continue for the duration of the forecast period. It will be freezing down to glen levels.

Comments

Unstable windslab at low altitudes. This overlies weaknesses at depth which is bridged by hard windslab. Steep rollovers especially affected.
